Dear Dr Townsend,

Re: Emma Johnson

I am writing to urgently refer, an 11-year-old female, whose symptoms and signs are indicative of a severe attack of asthma, triggered by an upper respiratory tract infection. Your expert assessment and management is appreciated.

On today's consultation, Emma presented with a 48-hour history of shortness of breathing and fever, associated with runny nose and loss of appetite. On examination, her throat was congested. Additionally, difficulty of breathing with use of accessory muscle was noticed, and a widespread wheeze was heard upon auscultation. Her PEFR was reduced to 140 L/min.

On the last six months, Emma has been diagnosed with asthma, for which she is receiving inhaled corticosteroid and ventolin puffer. She has no allergies. Her family history is significant for bronchial asthma.

Based on the above, ventolin nebulisation was commenced with slight improvement in her condition. Hence, she has been referred to your professional evaluation and treatment. Please do not hesitate to contact me if you need any further information.

Yours sincerely,
Doctor
